Skeletal System worksheet

Section A: Intro to Skeletal System
The skeletal system performs vital functions that enable us to move through our daily lives.
- **Support** - The skeleton provides support and shape to the body.
- **Movement** – Bones enable body movements by acting as levers and points of attachment for muscles.
- **Protection** - The skeleton protects vital organs from damage, encasing them within hard bones.
- **Blood Cell Production** – The production of blood cells (hematopoiesis) occurs in the red marrow.
- **Storage** - Bones serve as a reservoir for calcium and phosphorus which is essential for cellular activities.

1. How are bones involved with body movement? ____________________________________________________________

2. Why is protection and support of the skeletal system a vital function? ___________________________________________

3. What is hematopoiesis and where does it occur in the bone? ________________________________________________

4. What minerals are stored in bones? __________________________________________________________________

Section B: Functions & Classification
1. Explain how the skeletal system performs the following functions.

<table>
<thead>
<tr>
<th>Function</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Support</td>
<td></td>
</tr>
<tr>
<td>Protection</td>
<td></td>

</tr>
</tbody>
</table>

2. How many bones are located in an adult human skeleton?________________________________________________________

3. Which bones form the axial skeleton? ________________________________________________________________

4. Which bones form the appendicular skeleton? __________________________________________________________

5. Color the appendicular skeleton **BLUE** and the axial skeleton **RED**.

➢ Use this link to help learn the bones of the skeleton.
  [https://www.wisc-online.com/learn/health/medical-assistant/mea304/the-skeleton--bones---joints](https://www.wisc-online.com/learn/health/medical-assistant/mea304/the-skeleton--bones---joints)
6. Label the bones on the skeleton. sacrum, coccyx, pelvis, cervical vertebrae, thoracic vertebrae, lumbar vertebrae, cranium, mandible, humerus, ribs, sternum, clavicle, scapula, radius, ulna, carpals, phalanges, metacarpals, femur, tibia, fibula, patella, tarsals, metatarsals, calcaneus, phalanges

7. Fill in the missing information on the chart.

<table>
<thead>
<tr>
<th>Bone</th>

8. What are the functions of bone markings? _______________________________________________
____________________________________________________________________________________
Section C: Bones Tissue

Compact and spongy bones are considered the two basic bone types. In a long bone, spongy tissue is found at the ends while compact can be found at the outer layer and shaft of a long bone. In other type of bones, spongy fills the inside and compact forms the outer layers.

- Compact bone is made of osteons (Haversian systems) which form longitudinally within the bone. These osteons form the structure of compact bone. Osteons have a central canal which carries vessels and nerves. Compact bone is heavy, extremely tough and forms in layers. It accounts for more than 75-80% of the entire skeleton.
- Spongy (calcceullous) bone consists of a lattice of thin threads of bone called trabeculae. It is less dense than compact bone. The orientation of trabeculae is affected by exposure to mechanical stress. Trabeculae bone gives supporting strength to the ends of the weight-bearing bone.

1. Compare and contrast the two types of bone tissue – spongy and compact. Include structure, location and arrangement of cells, functions and any other characteristic.

<table>
<thead>
<tr>
<th>COMPACT</th>
<th>SPONGY</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>

</tbody>
</table>

Section D: Macroscopic Anatomy

1. Using the key choices, identify the following statements relating to long bones.

Diaphysis  Medullary cavity  Epiphyseal plate  Red marrow  Osteoblast
Epiphysis  Articular cartilage  Periosteum  Endosteum  Osteoclast

a. __________________ Location of spongy bone in a long bone
b. __________________ Location of only compact bone in a long bone
c. __________________ Site of hematopoiesis in the adult
d. __________________ Cells that form bone
e. __________________ Cells that destroy bone
f. __________________ Bone shaft
g. __________________ Membrane lining trabeculae and internal compact bone
h. __________________ Outer membrane covering compact bone
i. __________________ Site of fat storage in the adults
j. __________________ Site of longitudinal growth in a child
k. __________________ Ends of a long bone
l. __________________ Covers the epiphysis to provide cushion between bones
m. __________________ Provides anchoring points for ligaments and tendons
n. __________________ Contains osteogenic layers consisting of osteoblasts and osteoclasts

__________________

EPIPHYSIS (end) (a), EPIPHYSIAL LINE (a) - purple
The epiphysis is the end of a long bone. Externally it has a thin layer of compact bone, while internally the bone is cancellous. The Epiphysis is capped with articular cartilage.

DIAPHYSIS (shaft) (b)
The diaphysis is the shaft of the long bone. It has compact bone with a central cavity.

ARTICULAR CARTILAGE (c) - green
The articular cartilage is found on the ends of long bones. It is smooth, slippery, and bloodless.

PERIOSTEUM (d) – dark blue
Periosteum is a fibrous, vascular, sensitive life support covering for bone. It provides nutrient-rich blood for bone cells and is a source of bone-developing cells during growth or after a fracture.

CANCELLOUS (spongy) BONE (e) and MARROW (e) – light blue
The cancellous bone appears as tiny beams of bone arranged like a lattice. Red marrow packs the spaces between beams.

COMPACT BONE (f) - pink
The compact bone is a dense bone found in the diaphysis. Its repeated pattern is arranged in concentric layers of solid bone tissue.

MEDULLARY CAVITY (g), YELLOW MARROW (g) - yellow
The medullar cavity of the diaphysis serves to lighten bone weight and provide space for its marrow.

NUTRIENT ARTERY (h) - red
Each long bone contains a tunnel in its shaft for the passage of a nutrient artery, which supplies the shaft.

Section E: Gross Anatomy Concept Check
1. Explain how the function of the endosteum and the periosteum.

___________________________________________________________________________________

2. Which type of bone contains osteons? ____________________________

3. Which type of bone contains trabeculae? _________________________

4. What’s the membrane lining the medullary cavity called? ____________

5. What’s the membrane lining the diaphysis called? ________________

6. Describe the location of spongy and compact bone in a flat bone. ________________

___________________________________________________________________________________

7. Where are the osteogenic layers of osteoblast and osteoclast found? ______________

___________________________________________________________________________________

8. What is the function of the epiphyseal plate? ____________________________

___________________________________________________________________________________

9. In an adult long bone, where are the location of yellow marrow and the location of red marrow?

___________________________________________________________________________________
10. Label the long bone diagram.
   a. __________________________
   b. __________________________
   c. __________________________
   d. __________________________
   e. __________________________
   f. __________________________
   g. __________________________
   h. __________________________

➤ Long Bone Structure: http://media.pearsoncmg.com/bc/bc_marieb_happlace_7 labeling/fig_0603.html

Section F: Microscopic Anatomy
1. Mature bone cells, called __________________________ maintain bone in a viable state.
2. __________________________ are stem cells that divide by mitosis & are located under the membranes.
3. __________________________ causes calcium to be deposited in bones as calcium salts.
4. Bone cells that liquefy matrix and release Ca+ to the blood are called __________________________.
5. What materials form the matrix that surrounds bone cells? __________________________
6. What type of cells divide and differentiate into osteoblast or osteoclast? __________________________
7. Lacunae arrange themselves in concentric rings called __________________________.
8. What is the structural unit of compact bone? __________________________
9. What are the small cavities that contain osteocytes called? __________________________
10. The __________________________ is the central canal running vertically in an osteon.
11. What canal connects the periosteum to the Haversian canal? __________________________
12. What canal connects lacunae to each other and to the Haversian canal? __________________________
13. Label the diagram.
   a. __________________________
   b. __________________________
   c. __________________________
   d. __________________________
   e. __________________________
   f. __________________________

➤ Micro of a long bone: http://media.pearsoncmg.com/bc/bc_marieb_happlace_7 labeling/fig_0606.html
Section G: Bone Growth & Remodeling

_Growth in length:_ A sequence of steps occurs for bone to grow longer at the epiphyseal plate. At the plate, chondrocytes first produce hyaline cartilage. The cartilage then becomes calcified or ossified to form hard bone tissue (involves addition of Ca+ and Phosphorous ions). The chondrocytes produce cartilage on one side of the plate and push the end of the bone up. The other side of the epiphyseal plate gradually becomes calcified. Once a person reached adulthood and the bones have reached maximum length, and the whole plate gets calcified. It forms a visible line called the epiphyseal line.

_Growth in diameter:_ Making a bone grow in diameter is a more straightforward process. To make a bone thicker, just add new bone tissue to the outside. Osteoblasts on the periosteal side add bone to increase diameter and osteoclasts on the endosteal side remove some bone tissue resulting in a wider medullary cavity. It’s important to take excess bone tissue away from the inside otherwise bone would get too thick and fill completely with bone tissue.

_Bone Remodeling:_ There is a tremendous amount of activity by bone cells throughout life to maintain healthy bone and keep it from getting brittle. As old bone tissue gets hard and brittle so it must be removed and new tissue replaces the old. This process is stimulated in response to stress (like any exercise). Thus bone is reshaped when exposed to gravity by placing weight on it.

1. Where does bone growth to increase length occur? __________________________________
2. What do chondrocytes produce? ____________________________
3. When bones stop growing in length, what is left? ____________________________
4. How do bones grow wider? _________________________________________________
5. What prevents bone from becoming too thick and completely filled with bone tissue due osteoblasts on the periosteal side? ____________________________
6. Do bones activity stop when you finishing growing? Explain your answer. __________________________________________
7. What factors stimulate bone remodeling? __________________________________________

Section H: Bone Development, Growth & Remodeling

1. When does osteogenesis occur in an embryo? ____________________________
2. What is intramembranous ossification? ____________________________
3. What is endochondral ossification and where does it occur? ____________________________
4. When babies are born ossification is complete for the most part except for the hyaline cartilage founding the articular cartilage and epiphyseal plate. Why is it vital that the hyaline cartilage in these two areas NOT prematurely ossify? ____________________________
5. In your own words, explain how bones grow in width. __________________________________________
6. During remodeling, what cells cause bone deposition? ____________________________
7. During remodeling, what cells cause bone reabsorption? ____________________________
8. During remodeling, most bone reabsorption occurs under the ____________________________.
9. During remodeling, most bone deposition occurs under the ____________________________.
10. New cartilage continuously divides, matures and is ossified. What replaces this ossified cartilage cells? ____________________________

Section I: Factors Affecting Bone Growth/Remodeling

1. Briefly explain how mineral balance is important for bone growth. __________________________________________
2. Explain how osteoblastic activity is stimulated by hormones.

Rising blood Ca+ levels Stimulates ____________ gland To produce ____________ hormone ____________ (cells) deposit Ca+ salts in bone
3. Explain how osteoclastic activity is stimulated by hormones.

Falling blood Ca+ levels \(\rightarrow\) Stimulates \______________\ gland \(\rightarrow\) To produce \\
\______________\ hormone \(\rightarrow\) \______________\ (cells) to break down bone matrix \\
and release Ca+ salts into blood

4. Besides PTH and calcitonin, what other hormones influence bone growth?

5. How is the bone tissue of a person that is active and working out different than that of an individual that is sedentary “couch potato” or bedridden?

6. What happens to your bones as you age?

Section J: Calcium Metabolism -- Alcohol Disrupts the Balance in Your Body

What does alcohol do to bone metabolism?

Even one night of drinking causes temporary PTH deficiency and increased urinary calcium excretion. This means you lose calcium from your body. Furthermore, if you choose to drink chronically, vitamin D metabolism will be obstructed, and thus you will not be able to absorb calcium that you get from your diet. Several studies indicate that alcohol is directly damages the cells that form your bones and indirectly contributes to nutritional deficiencies of calcium or vitamin D. Alcohol also indirectly causes inefficient bone metabolism through liver disease and altered levels of reproductive hormones.

Why are alcoholics more likely to suffer from bone disease?

Alcohol makes it difficult for calcium to be absorbed from the gastrointestinal tract. This causes serum calcium levels to fall which feeds back to parathyroid glands resulting in an increase secretion of parathyroid hormone (PTH). This increase in PTH then leads to calcium resorption from bone causing demineralization of bone and osteoporosis bone disease. PTH could also directly inhibit bone-forming cells called osteoblasts. As you may recall from the effects of alcohol on the reproductive organs, alcohol reduces testosterone levels. Reduced testosterone levels cause bone demineralization; many studies have indicated that androgens in the male are necessary for preserving bone mass. Low testosterone levels that are induced by alcohol use may cause osteoporosis which then leads to the greater possibility of breaking your bones.

http://www.montana.edu/wwwai/imsd/alcohol/Vanessa/vwcalcium.htm

1. How does alcohol affect bone metabolism? 

2. Why are alcoholics more likely to suffer from bone disease?

Section K: At the Clinic

1. A doctor has just viewed the x-rays of a 12 year old male and has found that where the growth plate should be is instead filled with what seems to be newly formed compact bone. The doctor has diagnosed the boy with premature ossification of the epiphyseal plate. What effects if any will the doctor now need to share with the parents related to their son’s future growth?

2. Jessie fractured her tibia. The orthopedic surgeon tells her the fracture is nondisplaced, open and complete. Describe the fracture based on the surgeon’s diagnosis.
3. A 75 year-old woman and her 9 year old granddaughter were in a train crash in which both sustained trauma to the chest while seated next to each other. X ray showed that the grandmother had several fractured ribs, while her granddaughter had none. Explain these surprisingly different findings.

4. Bernice, a 75 year old woman, stumbled slightly while walking then felt a terrible pain in her left hip. At the hospital, X rays revealed that the hip was broken. Also, the compact and spongy bone throughout her spine was very thin. What was her probable condition?

5. A middle-aged woman comes to the clinic complaining of stiff, painful joints. A glance at her hands reveals knobby, deformed knuckles. What condition will she be tested for?

6. Patient X has a tumor of the thyroid gland that causes a hypersecretion from this gland. Predict the effect on the skeletal system and on the secretion of calcitonin.

7. After being picked up from the Atlantic Ocean after ‘splashdown’, the American astronaut team was brought to the Naval Hospital for checkups. X rays revealed decreased bone mass in all of them. Isn't that surprising in view of the fact that they do exercises in the capsule while in space? Why or why not?

8. Where would you find these 3 types of joints?
   a. Synarthrotic -
   b. Amphiarthrotic -
   c. Diarthrotic -

Section L: Learning from Skeletons

Skull - Look for the sagittal suture – the squiggly line that runs the length of the skull – and note whether it's completely fused. If it is, the remains are likely to be of someone older than 35. Look for a second line at the front of the skull -- the coronal suture -- which fully fuses by age 40.

Teeth - They can determine how old a person was at death, what kind of health they were in and what kind of diet they had.

Pelvis - Look for the pubic symphysis, which is the joint located in the pelvis. The older the person at death, the more pitted and craggy these bones will be. Check if there are any soft marks on the cartilage which are left by childbirth as the bones soften to allow easier birth. To identify gender, assess the pelvis shape; men have a narrow, deep pelvis and women a wider, shallower pelvis, better-suited to carrying a baby. For a quick identification in the field, a forensic anthropologist will find the notch in the fan-shaped bone of the pelvis and stick their thumb into it. If there’s room to wiggle the thumb, then it’s a female; if it’s a tight fit, it’s the skeleton of a man.

Wrist - Examine the wrists, as bones often hold clues to the primary work of the decedent. Bony ridges form where the muscles were attached and pulled over the years. A forensic anthropologist might find a bony ridge on the wrist and decide the dead person may have been someone who used their hands for a living.

1. How can the skull be used to determine age?
2. What can teeth tell you about the deceased?
3. How is the pelvis of a female different from a male?
4. What information about the deceased can you derive from the bones in the hand?
